INTRODUCTION

This report is a summary of data collected from a variety of sources concerning coho salmon, *Oncorhynchus kisutch*, in the northern California portion of the Southern Oregon-Northern California Evolutionary Significant Unit (SO-NC ESU). Data concerning both juvenile and adult fish have been collected and are presented in the stream list database, Appendix 1, which represents an updating, for the streams of the study area, of a list prepared earlier for the National Marine Fisheries Service (NMFS) (Brown and Moyle 1991).

We agree with the NMFS that “Coho presence-absence data needs to be collected over three consecutive years” (from the statement of work in NMFS' "request for quotations" for this project) and we have designed this study accordingly, as though it were the first year of three, in the hope that future researchers will find it easy to build upon. Given the large number of streams in the study area, particularly in Del Norte County, which have yet to be surveyed (Brown and Moyle 1991), it would take several field seasons to generate a map to accurately represent coho salmon distribution in the entire area.

A presence-absence study such as the one reported here, while a logical precursor to fish abundance studies, has a definite unevenness. Presence - a sighting of even one of the fish in question by a qualified observer - is an absolute result regardless of the protocol used to obtain it. Absence, on the other hand, can only be established as a probability and must, therefore, be determined using a protocol of suitable rigor. Presence data is therefore easier and cheaper to acquire than absence data, and for that reason a preponderance of the data in Appendix 1 is presence data. Absence data gathered through protocols as rigorous as the ten pool protocol required in the field-work portion of this study were hard to find.

METHODS

The study area extends from Punta Gorda near the Mendocino-Humboldt county line north to the California-Oregon border and it includes all of the watersheds that drain to this stretch of the coast. The land ownership in the study area is roughly half federal, half non-federal. The study area involves all or part of seven California counties. Del Norte, Humboldt, Siskiyou, Trinity and Mendocino counties account for nearly all the area. Two of the study area streams, Black Butte Creek (middle fork Eel River) and Lake Pillsbury (upper Eel River), are in Glenn and Lake counties, respectively. Coho salmon populations in the project study have been determined by NMFS to have greater similarity with one another than with the coho populations found south of Punta Gorda.

Historical presence and absence were established through a wide variety of literature, with the two principal sources being Brown and Moyle (1991) and Hassler et al. (1991). All other sources are listed in the database with the stream or streams for which they have identified coho presence or absence (Appendix 1). In using Brown and Moyle (1991) and Hassler et al. (1991) we tried to provide, in the database's “source”

column, the original authority. For example, if Brown and Moyle cited Hassler and Hassler cited Boberg and Kenyon (1979), then we identified Boberg and Kenyon as our authority. Where Hassler or Brown and Moyle made original additions of their own they were cited. This provides a more accurate dating of each stream record and enables database sorting, by date of record, to support whatever definition of “historic” or “sufficient to establish presence” one cares to apply.

We first gathered current presence-absence data through consultations with state and federal resource agencies, landowners, industry groups, tribal fisheries departments and individual researchers. A special effort was made to solicit assistance from private landowners. Fruit Growers Supply Co., Timber Products Co., Georgia Pacific, and others provided invaluable assistance in the form of data, stream access, or both. Again, while we could accept presence data gathered under any reasonable protocol, we did not include absence data unless it was gathered using a protocol at least as rigorous as the ten pool protocol specified for our field-work plan. Since this requires the sampling of at least ten pools, spaced throughout the lower, middle and upper reaches of the anadromous portion of the watershed, data from such rigorous surveys were rare. As a result, we obtained little new and useable absence data through our consultations.

We next added to the current presence-absence data that which we gathered through our own stream surveys. We performed stream snorkel surveys during the months of July, August and September 1998. Late rains and high flows made sampling earlier in the year impossible. The pools we surveyed were as close as possible to the shaded, low velocity pool with woody debris considered ideal for the rearing of juvenile coho. At each pool sampled, the counting of coho and steelhead were the priority, but other species were often included in the observations, as well. When the fish counts were completed we next recorded pool length along the thalweg; mean width at three transects; mean depth taken along the three width transects, and a narrative describing the habitat. All measurements were taken to one-tenth of a foot. Air and water temperatures were recorded at intervals throughout the day. (Appendix 3, Field sheets)

If coho were located, the discovery site was recorded by township, range and quarter-section, and measurements of the habitat were made to complete the survey of that stream. We divided our time among the watersheds of concern according to their size and accessibility. In each watershed we gave priority attention to those streams which, with the inclusion of our survey, would yield the longest data set. For a more detailed explanation of our watershed prioritization scheme see Appendix 2, the field workplan and watershed prioritization scheme.

RESULTS

We found that within the northern California portion of the Southern Oregon-Northern California ESU, coho salmon were absent from 31% of the historical-record streams for which there is current (i.e., 1996 to 1998) data (Table 1). We were able to collect current data through our consultations with other investigators and our own stream survey efforts for a quarter of the historical-record streams. Of the 97 historical-record

streams for which we obtained current data, coho salmon were absent from 30 and were present in 67. We believe that that absence rate is conservatively low because of the rigorous data screening standards we discussed earlier. Perhaps a more meaningful number would be that we obtained from our surveys of historical-record streams. Again, once we entered a stream we either established presence or we searched the requisite ten pools before claiming absence. The coho salmon absence rate obtained from historical-record streams in this manner was 54%. We also compiled coho salmon presence data for 123 streams lacking any prior coho presence record. For 27 of these streams there is current, 1996-98, data.

Historical-record streams in Del Norte County, for which we have current data, were found to be coho-absent 42% of the time (10 of 24). This number shoots up to 60% when determined by our 1998 stream surveys alone. Coho salmon were found in four Del Norte streams having no historical coho records. The dominant watershed of historical record for Del Norte County is the Smith River. The Smith River does not have a large coho salmon run (Waldvogel 1988), but the run has been consistent ever since Waldvogel began his observations in 1980.

In Humboldt County, historical streams for which we have current data were found to be coho-absent 3% of the time (1 of 30). This number drops to 0% when derived from our 1998 surveys alone. Because of its large private land holdings Humboldt County does not offer good opportunities to survey entire streams for proof of coho absence. Consequently, virtually all data is presence data - which artificially deflates percent absence. Coho salmon were found in eleven Humboldt County streams with no historical records - the highest number of any county. This is not unexpected since Humboldt County's total number of historical-record streams is also the highest because it includes parts of the Eel and Klamath river systems, as well as a number of smaller coastal streams. The Mattole River, which is entirely within Humboldt County, still supports a small coho salmon run, as it did historically. We found coho salmon in four Mattole River tributaries lacking historical coho occupancy records.

Historical-record streams in Siskiyou County for which we have current data were found to be coho absent 52% of the time (16 of 31). This rises to 72% when derived from our 1998 surveys alone. Coho salmon were found in seven Siskiyou County streams with no historical records. The dominant watersheds of historical record for Siskiyou County are the Klamath and two of its mid-section tributaries, the Scott and Shasta rivers. Coho salmon were historically abundant in the Klamath's lower tributaries (Brown and Moyle 1991).

Examination of California Department of Fish and Game warden diaries from the 1950s shows coho salmon in virtually every upper Klamath and Scott stream with a ditch and hayfield. The Scott River, prior to a federally-funded "channel improvement" project through the Scott River Valley, was a low velocity, meandering stream, ideal for coho salmon. The modified Scott River ushers the water out of the valley far too quickly for coho. This channel modification, in conjunction with the multitude of wells in the Scott Valley, is dropping the water table. Many of the Scott Valley's historical-record streams

are entirely dry in their lower reaches for much of the year. The Shasta River shows relatively consistent runs from the 1950s up to 1984, at which point numbers dropped severely to a low point which has become the new norm.

In Trinity County historical-record streams for which there is current data were found to be coho absent 25% of the time (1 of 4). This stays at 25% when derived from our 1998 surveys alone. Both these numbers are probably low because of the lack of current data for the South Fork Trinity River. Coho salmon were found in one Trinity County stream that lacked historical coho records. The dominant watershed of historical coho records for Trinity County is the Trinity River. In the mainstem Trinity coho salmon go all the way to Lewiston Dam, the head of anadromy. In the South Fork Trinity they appear to make it only as far as Madden Creek and have not been seen above this point for many years. The tributary streams above Lewiston and Trinity River dams look more like coho streams than the tributaries coho now use below the dams.

Historical-record streams in Mendocino County for which we have current data were found to be coho absent 25% of the time (2 of 8). This number shoots to 100% when derived from our 1998 surveys alone. Mendocino County, like Humboldt County, has a high percentage of private land ownership, which increases the difficulty of obtaining absence data in sufficient quantity to accurately represent coho salmon distribution. Coho salmon were found in four Mendocino County streams with no historical records. The dominant watershed of historical record for Mendocino County is the Eel River. Records indicate widespread historical use of the Eel River drainage by coho salmon (Brown and Moyle 1991). Even though the Eel was reported to contain the largest wild population of coho salmon in California, it is not clear that that is the case today (U.S. Heritage Conservation and Recreation Services 1980). Present coho use is greatest in the South Fork Eel, even though salmon counts at Benbow Dam on the South Fork have declined steadily since the 1930s. Several tributaries to the main Eel are used by coho to a lesser degree.

Again, Glenn County was included because of Black Butte Creek, which flows into the Middle Fork Eel and has no historical record of coho salmon use. Lake County was included because it contains the last reach of the Eel River before Lake Pillsbury. We obtained no new data from this area.

Table 1. Summary of Appendix 1, historical and current presence and absence data for coho salmon, *Oncorhynchus kisutch*, from the Northern California portion of the Southern Oregon–Northern California Evolutionary Significant Unit. Historical data were from literature only. Current data was derived from stream surveys performed during 1996, 1997 and 1998. One column lists the percent absence of coho from the historical-record streams surveyed by Kier Associates in 1998. The final column shows the number of non-historical-record streams for which the authors located current presence data.

Area	Historical-record streams	Current-data streams	Number of streams from which coho were absent	Percent absent, historical-record streams	Percent absent, Kier surveys of historical-record streams	Non-historical-record streams for which there is current coho presence data
Del Norte	67	24	10	42	60	4
Humboldt	185	30	1	3	0	11
Siskiyou	53	31	16	52	72	7
Trinity	16	4	1	25	25	1
Mendocino	66	8	2	25	10	4
Glenn	0	0	0	-	-	0
Lake	1	0	0	-	-	0
Total	388	97	30	31	54	27

DISCUSSION AND RECOMMENDATIONS

The current (1996 to 1998) coho salmon presence-absence data captured in this report is largely presence data, since presence data can be accepted from qualified observers using virtually any method. Absence data, on the other hand, must have been collected using protocols of rigor comparable to the ten pool protocol, and such surveys are rare. The percent absence for historically-occupied coho streams calculated from the current data set (31%) understates absence. The 43 watershed surveys the authors completed in 1998 yield a 54% absence of coho from historically-occupied streams. We regard that figure to be more accurate than the 31% absence figure simply because we took the time to do full stream coho absence surveys. Our stream surveys also yielded coho in eight streams for which there were no historical presence records.

We located coho salmon presence records for 123 streams that were without prior coho presence records. For 27 of these there is current data, i.e., that which falls within the 1996 to 1998 period. This would suggest that the historical record in current use, Brown and Moyle 1991, may not be the most appropriate baseline for future presence-absence surveys. An improved list could be created under whatever chronological definition of "historic" is considered appropriate simply by sorting the database (Appendix 1) presented here by record date and coho salmon presence.

There is also an indication that streams that do not belong there have found their way onto the Brown and Moyle list. Rattlesnake Creek, a tributary to the Middle Fork Eel River is a good case in point. A series of 12- to 24-foot waterfalls cascade all the way down to the mouth of Rattlesnake Creek (Appendix 3 - field data sheets), suggesting that this never was a coho stream. A protocol is needed for culling such streams from the list of historically coho-occupied streams.

We feel the ten pool protocol provides sufficient coverage for the declaration of absence, while presence, again, can be accepted under any protocol. For improved coverage for the dollar we suggest the following modifications. Count fish only when you locate coho salmon and note the location. When you do not locate coho salmon, simply note the location of the pools surveyed. Two-person teams, freed of measuring tools and superfluous measuring tasks, could cover a lot more ground, establishing presence and declaring absence as surely as the full ten pool protocol used in this study.

Coho salmon distribution is dynamic. The NMFS recognizes the ability of coho salmon to both faithfully return to their natal streams and to recolonize newly-accessible habitat (NMFS 1995). When necessary, coho will bypass their homestream waters and spawn elsewhere, as they did in the Kalama River when the eruption of Mt. St. Helens destroyed historic coho habitat in the Toutle River.

We located coho salmon in Salt Creek, a tributary of Horse Creek in the mid-Klamath River region, during 1998. For the preceding ten years Salt Creek offered only damp rocks during summer, certainly no coho salmon. In 1998, with ample flow,

Salt Creek held coho salmon. A coverage greater than the 25% of historically-occupied streams which we accomplished in 1998 is needed to track such a dynamic coho distribution. A project twice the size of ours, with a slimmed-down ten pool protocol, would provide proper coverage for the tracking of the dynamic edges of coho distribution. Such a project would enable surveys to be made of a majority of the accessible streams from the historically coho-occupied list.

APPENDIX 1

Streams in the northern California portion of the Southern Oregon-Northern California ESU for which there is coho salmon presence-absence data, listed as they occur along the coastline, running north to south.

- The STREAM column contains the name of the stream being reported.
- DATE is the date of the literature or survey.
- The TYPE column lists LIT for literature, UD for unpublished data, agency acronyms such as CDFG or USFS, where appropriate, and KIER for the firm's 1998 stream survey.
- A “Yes” in the HIST column indicates those streams which have there is an historical record of coho salmon occupancy.
- The COHO column lists whether the data indicates coho salmon to be present or absent
- The S or J column tracks spawner vs. juvenile data.
- # COHO, # STEELHEAD, # POOLS and COHO LOCATION were filled in when possible.
- COUNTY is for the County in which the data was gathered.
